

Throughout these past two weeks of ENG-95 I have learned a lot more. I learned the essentials of coding. I have no background in coding what so ever but I am still enjoying everything and I think I am keeping up pretty well. Whenever I run into a problem I know that talking to my blue rubber duck can help but to avoid the problem I know that proper planning saves a lot of troubleshooting time. Next I learned the pin layout for the arduino we will be using in the lab and how to write proper prompts to effectively achieve my goal. I can find the arduino a little confusing sometimes but luckily I have good group mates and I just ask them questions on anything. I think the arduino looks like a toy I wanted from my childhood called a Hex Bot.

After that we played around with breadboards and blew a resistor up. I thought we messed up and we might get in trouble for destroying lab equipment but then everything was on purpose so I laughed it off. I then learned that it is important to have a fail safe so I don't explode my whole project and cry because my hard work is ruined. However, it was fun prototyping a version of an alarm system with my group. Finally, we spun a servo and took measurements with a sensor. We wrote a program to take accurate measurements and put it all in a spreadsheet and I learned a couple of new tricks. I thought spreadsheets were for business majors but then I remember that anything a business major can do an engineer definitely can do too.

(Engineering>Business) I am curious what the next week entails as we get into more complicated applications and bigger projects since everything has been able to get done in a single class period instead of being across several days.
