

In our last week of class we wrapped up our projects with a demonstration and a presentation of our prototypes. Although a little sad I can't go back to the key sight lab to continue finding ways to make our design better, I had so much fun building in the first place. I was in charge of the mechanics of our "Auto Ventilation System". I experimented with different folds and methods of attaching the string to the paper door to have the paper lift the most with the least amount of string pulled. Then I went about creating the fan which didn't have much thought but if need be I was going to research which certain blade orientation is most aerodynamic. I also created the housing for the fan trying to be mindful of the most efficient way of having the inside be aerodynamic and "air tight". I then attempted to make it look like Domo-kun which I have no idea of who he is but my girlfriend Giselle thinks he's cute so I decided to model the prototype to visually resemble him. Finally I worked hard to add like 35 animations to our presentation to visualize the project plan for the presentation.

I learned that working on teams can be fun even if it doesn't feel fair at first. We divided the work in three sections: code, electrical, and mechanical. The coding section looks like the obvious easy option because AI is more than capable of writing the code we need to bring our project to life. Reflecting on this I should have spoken up and not left it to my assumption that my teammate will help our harder jobs after just copying and pasting code from an AI model. Also I wish I had more time to conduct research before I had to build the system because I realized I misinterpreted my application of Bernoulli's principle. I initially believed that air rushed from low pressure to high pressure areas but it is the other way around so I would have to invert the cone to properly apply this idea. I live and learn and I am very excited to see what else I get to build.
